Measure of the health of a player's chip stack in poker
In no-limit or pot-limit poker,
a player's M-ratio (also called "M number", "M factor"[1] or just "M") is a measure of the health of a player's chip stack as a function of the cost to play each round. In simple terms, a player can sit passively in the game, making only compulsory bets, for M laps of the dealer button before running out of chips. A high M means the player can afford to wait a high number of rounds before making a move. The concept applies primarily in tournament poker; in a cash game, a player can in principle manipulate his M at will, simply by purchasing more chips.
A player with a low M must act soon or be weakened by the inability to force other players to fold with aggressive raises.
The term was named after Paul Magriel.
Calculation [edit]
The M-ratio is calculated by the formula:
M = stack small blind + big blind + total antes

$$M=\frac{\mbox{stack}}{\mbox{small blind}+\mbox{big blind}+\mbox{total antes}}$$

For example, a player in an eight-player game with blinds ofR$50/$100, an ante ofR$10, and a stack ofR$2,300 has an M-ratio of 10:
M = 2300 50 + 100 + (10 × 8) = 2300 230 = 10

$$M=\frac{2300}{50+100+(10\times 8)}=\frac{2300}{230}=10$$

That is, if the player only makes the compulsory bets, he will be "blinded out" of the game in 10 rounds, or 80 hands.
Dan Harrington studied the concept in great detail in

Harrington on Holdem: Volume II The Endgame, [2] defining several "zones" in which the M-ratio may fall:[3]

Zone name M-ratio "Optimal" strategy Green zone M 20 Most desirable situation, freedom to play conservatively or aggressively as you choose[4]
