### **O Que Eu Fiz Para Piorar Minha Situação: A Consequência do Jogo Falho**

Uma tarde de almoço, eu estava sentado em Descubra o Mundo das Apostas com o 7Games App! um café e olhando o aplicativo da 7Games no meu celular. Sem perceber como as horas passavam, pensei que poderia tirar minha próxima jogada antes do fim do dia. Fui para a tela de início e sem pensar duas vezes, descarreguei uma série de apostas em Descubra o Mundo das Apostas com o 7Games App! várias partidas diferentes - da sorte às corridas esportivas. Não percebi que minha decisão estava sendo tomada com base naquilo que estavam mostrando nas telas e não no meu conhecimento prático das maneiras como as apostas funcionam. As writers of this article are no exception, so we will start our story with a personal anecdote about one of the authors' experiences during his days as an undergraduate student at the University of Alabama. During my first year of college, I lived in a dormitory and was attending classes that were held on campus. One afternoon after class, while walking to the student center to buy some food for dinner (I had just discovered Chick-fil-A), an unfortunate incident happened. As I entered the parking lot between two buildings, one of my sandals broke apart and a sharp metal piece went into my foot. Without knowing what to do or where to go, all I could think about was how much pain this injury would cause me. So, in an attempt to ease the agony, I removed the metal piece from my foot as best as I could (unfortunately without any proper knowledge on first aid) and tried putting it back into my shoe. After spending a couple of minutes trying to hold it in place while walking across campus, I finally made it home and was able to seek medical attention there. Although the injury itself turned out not to be as bad as I had originally thought (thankfully), what did end up being worse is that my foot started turning an odd shade of red after a couple days passed. I eventually learned from a friend who majored in biology at UA why this was happening, and it made me wonder how many other people are unaware about the dangers or consequences associated with their everyday actions. In our modern world full of technological advancements, we often forget that there is still much to learn from nature itself – especially when looking for answers to a problem like mine (and others). This is where research on natural products comes into play. The term “natural products” can be defined as organic compounds derived directly or indirectly from plants, animals and microorganisms. Such substances are usually produced in small quantities by living systems through biochemical processes that occur over millions of years to produce their final structure (Figure 1). In the field of research on natural products, scientists have been studying a variety of organic compounds found in nature for centuries now; however, it was not until about one hundred years ago when they began focusing more intently on them. In this article, we will explore their

significance and importance to our everyday lives – both past and present – by providing insight into what is being done today with natural products research (NPR), how these studies can help solve problems like the ones faced in my college days (and others) as well as some of their future applications that could prove beneficial for humanity. Before delving deeper into NPR, it might be useful to understand why studying compounds found in nature is necessary at all; so let's take a quick look back over history first and examine how we got here from there: The History of Natural Product Research: A Short Timeline - Ancient Times (~10,000 B.C.): The use of plants for medicinal purposes can be traced back to this era; one such example is the Sumerians who used thyme and oregano as remedies against headaches & inflammation during their time period. - Middle Ages (~500 – 1450): During these times, many of nature's most potent compounds were discovered by alchemists; some examples include quinine which is derived from the bark of the cinchona tree and used to treat malaria & willow bark that contains salicylic acid (a precursor for acetylsalicylic acid or aspirin). - Renaissance Period (~1400s – 1600s): This period saw a significant increase in scientific inquiry due to developments like the printing press & advancements made within mathematics, astronomy & physics. With these improvements came greater knowledge about chemical reactions occurring naturally around us which eventually led researchers toward isolating various compounds from nature itself. - Age of Enlightenment (~1600s – 1800s): This age witnessed a surge in discoveries made by scientists regarding medicinal properties found within plants, animals & fungi; notable examples include penicillin discovered by Alexander Fleming during World War II or the antimalarial drug quinine used extensively throughout history for its treatment against malaria. - Modern Era (~1900s – Today): Research on natural products has now evolved into what can best be described as a multidisciplinary field incorporating numerous sciences such as chemistry, biology & pharmacology; not only does it play an integral role within these disciplines but also helps solve many global issues faced today including environmental concerns (e.g., finding alternative sources for energy). Today's NPR: A Multidisciplinary Field Incorporating Many Sciences At present, research on natural products is a multidisciplinary field that incorporates various sciences such as chemistry, biology & pharmacology (Figure 2). It plays an integral role within these disciplines while also helping solve many of the global issues faced today; including environmental concerns like finding alternative energy sources among others. Due to its vast scope and impact on human health, it is no wonder that natural products research has become increasingly popular over recent years with numerous studies being conducted worldwide in order to uncover their hidden potentials (as mentioned earlier) which have proven beneficial for humanity throughout history; from treating diseases such as malaria using quinine derived from the bark of the cinchona tree back during colonial times through nowadays where scientists continue exploring similar applications with plant extracts containing antimalarial compounds (e.g., artemisia annua). In recent years, NPR research has also been instrumental in identifying novel drug candidates against various diseases including cancer & HIV/AIDS while improving our understanding towards how certain organisms interact with each other within their respective environments; such knowledge could potentially lead us down paths never thought possible before. Benefits of Studying Natural Products NPR research has been around for centuries and continues to offer many benefits in today's world: - Drug discovery & development – NPR provides access to a vast array of chemical structures that can be used as starting points or scaffolds within the drug development process. These natural compounds have historically been sources for successful therapeutic agents such as aspirin (acetylsalicylic acid), morphine derived from opium poppies, paclitaxel found in taxol-producing yew trees etc., thus making it crucial for researchers involved with this field. - Understanding biodiversity & ecology – Studying natural products helps scientists gain insights into the complexity of various organisms within their respective environments; how they interact together using these chemical compounds is essential knowledge in order to preserve our planet's diverse life forms while also discovering potential applications derived from such interactions. - Improved environmental sustainability – As mentioned earlier, natural products research can aid us towards developing more eco-friendly alternatives for various industries including agriculture & energy production which ultimately reduces negative impacts upon nature

as well as human health; thus playing an important role in promoting long term sustainability practices worldwide. Conclusion on Natural Product Research Today: A Multidisciplinary Field Incorporating Many Sciences In conclusion, natural product research (NPR) is a multidisciplinary field incorporating various sciences such as chemistry, biology & pharmacology with numerous benefits for humanity today including drug discovery & development; understanding biodiversity & ecology while also improving environmental sustainability practices worldwide. As we have seen throughout history and in recent times alike (e.g., artemisia annua being utilized against malaria), these organic compounds found naturally within plants, animals & microorganisms continue to provide us with valuable insights towards improving our quality of life through their medicinal properties; whether it be curing diseases or enhancing environmental conservation efforts for future generations. While much has already been accomplished in this area over the years there remains untapped potential that scientists around globe are now striving to harness by using cutting-edge technologies like bioinformatics & high throughput screening; making NPR an exciting field ripe with possibilities for those interested. So next time you go out and explore nature remember – every plant, animal or microorganism could hold the key to something extraordinary! And who knows what discoveries might await us tomorrow? It's up to each one of us (you included) not just as researchers but also stewards of our planet earth; let's work together towards making this world a better place through science.

One of the key factors in any assessment or evaluation is how accurate it can be described as being to its subject. This could mean the accuracy with which it reflects reality, but also whether a given system for evaluating something measures what we would want it to measure. For example, does an examination accurately show our students' true ability and knowledge? This article explores two distinct yet related issues: how well do evaluation methods work at identifying the actual performance of individuals or groups; and in which ways are those individual performances affected by external factors that can cause a disparity between what is being measured. The paper uses examples from educational assessment to illustrate these points, but we believe they

also apply widely in other fields like employee appraisal. The first issue deals with the accuracy of measurement systems themselves. In order for an evaluation system to be useful it must accurately reflect individuals' true performance or ability. An example would be a student who can answer all questions correctly on a test, but does so by memorising answers rather than understanding concepts. Such students have learned how to pass tests - not necessarily learnt the material itself (this is referred to as 'teaching to the test'). A teacher might well conclude that such a student has mastered course content when in fact they do not. The second issue deals with external factors which can influence performance, but are unrelated to true ability or knowledge of an individual: for example, how hard students study, whether their parents support them at home and so forth. Such variables affect the results obtained by a measurement system (in this case, tests). This is known as 'measurement error', whereby there may be inconsistencies between what people actually know and do, and how that is measured in practice. To illustrate these two issues we can use an example from educational assessments: multiple-choice tests for high school students. Typically such tests consist of a series of questions with each question having four possible answers (or more). Students are asked to select the correct answer or, in some cases, all that is required of them is whether they think an item on the test is true/false. We can make some general assumptions about these tests: firstly, students' scores would normally be based on a percentage of questions answered correctly; secondly, for any given question there will be one correct answer and three incorrect answers (there may also be more than four possible choices). The 'correctness' or accuracy of the test can thus be described by two factors: how well the score reflects true ability/knowledge ('validity'), as above; and the degree to which a given student's performance is reflected in their score (e.g. if a student performs consistently at 70% on all tests, then that score will also be accurate). Measurement error arises because there are many external factors which can affect test scores but have nothing to do with true ability or knowledge ('random error'). One such factor is guessing: how often students guess the answer without any real understanding of it. The more questions on a multiple choice test, and particularly where each question has four answers (or more), then the higher probability that at least one student will randomly select an incorrect answer by chance. Thus there is always some error in measurement - but this can be minimised with careful design of tests and other factors such as reducing test difficulty levels to lower guessing rates. Another factor affecting accuracy of measurements (in general) relates to the number of questions being used on a given assessment: for example, if we use only one question then there is no way to determine how well that student understands course material; and using too many questions can lead to measurement error caused by students' guessing or lack of familiarity with the content. Ideally test items should be designed so as to minimise both types of error (see Figure 1). Figure 1: Error in assessment measurements resulting from a single item question versus multiple-choice tests for high school students, whereby random and systematic errors are represented by red bars respectively; the 'true' ability score is shown with black lines. Another important issue is that of 'item difficulty'. Ideally all test questions should be matched to an appropriate level in order that they adequately reflect student performance on a given topic: for example, if a question asks students to identify which of two items are identical then this may be too difficult (even though it might appear simple), and so would require the use of more 'basic' test questions. Ideally such item difficulty should match up with overall student performance in the relevant subject area; that is, where students perform at a high level they will take tests which present challenges but not overly difficult material - while those who do less well may receive simpler questions to help them progress their skills and knowledge (see Figure 2). Figure 2: Item difficulty for two groups of test takers. The final issue deals with the overall structure or design of a testing system, including whether it is being used fairly in practice. For example, if an examination allows students to bring calculators but prohibits their use during tests then that would be unfair to some students (and so reduce validity). It may also not accurately measure performance: for instance, a student who has memorised all of the test questions and answers can succeed without actually understanding the material. It is clear from these examples how difficult it might be to construct an accurate measurement system that fairly reflects student ability in a given subject area; but this should not prevent us from trying (although we must always remember that

any assessment tool will have its limitations). In reality, almost all educational and other testing systems are imperfect - there is no such thing as 'perfection'! However, we can still construct assessments which minimise measurement errors to a reasonable extent. We believe the issues above apply widely in many areas where performance of individuals or groups needs to be measured; not just within education (and employee appraisal). Although educational and workplace testing systems may seem very different from each other on the surface, they share important underlying similarities. For example: both involve complex human behaviours which are difficult to measure accurately - despite our best efforts we can never 'measure everything'. Therefore, it is essential that tests (and other evaluation tools) have a good design and be used in ways that minimise measurement errors as much as possible. The next step then for educational assessments will involve using the findings of this paper to inform testing strategies within schools; or alternatively how they can use existing systems more effectively, if not improving them entirely! As we have shown above there is no 'silver bullet' solution: rather it requires a careful combination and blending of techniques in order to achieve better results. In summary: although measurement errors are an unavoidable reality for assessment purposes (even within the best-designed tests), these can be reduced through good test design, combined with other factors such as appropriate difficulty levels, use of calculators/computers and so forth; we must also remember that there is always a 'level playing field' in which all students should have an equal opportunity to demonstrate their understanding (or otherwise) within the constraints of each assessment. \*Blog post originally appeared on Myths & Realities: The Science of Education blog, where you can find other posts by researchers working at TIMSS& PIRLS International Consortium.
