Written by: Tayo Amegunde Posted on April 3, 2019. Last updated on November 25, 2019 How Do I Know If My Cat Has a Urinary Blockage? Urinary tract infections (UTIs) are relatively common and usually easy to detect with diagnostic tests such as a urinalysis or culture of the urine. However, some UTIs can be accompanied by more serious health conditions, including urethral obstructions (blockages). A blockage occurs when something gets stuck in your cat's urinary tract and prevents her from emptying her bladder completely. If a blockage persists, your cat could develop complications such as kidney failure. Early detection is crucial for successful treatment, so learning how to recognize the signs of an obstruction can help you keep your pet safe. What Causes Urinary Tract Obstructions in Cats? Urine flows through a series of tubes (ureters) that branch off from her kidneys and end at the bladder, where it is stored until she urinates. Most blockages occur when something becomes lodged inside these urethral canals, preventing your cat's urine from exiting her body completely. Urinary tract obstructions most commonly affect male cats because their ureters are shorter and narrower than those of female cats. Urethral blockages

may also occur when the muscles around your pet's bladder fail to contract normally, causing urine build-up in her bladder (a condition called a "distended bladder"). Urinary tract obstructions are usually caused by crystals or small stones that form from minerals and salts. Increased production of mucus may also play a role as some cats develop mucinuria, which is the presence of mucus in their urine. Other causes include urethral swelling (which can be caused by inflammation or neoplasia – abnormal growths) and congenital defects such as strictures, where portions of her ureters become narrowed due to scar tissue.

### What Are the Signs & Symptoms?

A blockage is a serious condition that requires immediate veterinary care because it can lead to irreversible damage within hours, particularly affecting your pet's kidneys. Because obstructions are rare and difficult for owners to spot, knowing what symptoms to look out for may help you get your cat the care she needs faster so her prognosis is better. Signs of a blockage include:

- Straining or struggling while urinating with no results (may also strain to defecate)
- Excessive licking and chewing at the perineal area (the area between your cat's hind legs), which indicates painful inflammation in that region.
- Urinating more frequently than usual, or producing only small amounts of urine when she does urinate. This is often accompanied by a strong odor and cloudy appearance to her urine due to the presence of bacteria.
- Vomiting (which may be bloody if there's irritation in your cat's lungs from swallowing small amounts of urine).
- A decreased appetite or lack of interest in food and water intake.
- Dehydration – this is caused by her not drinking enough water to compensate for the fluids she loses through vomiting, diarrhea (if present), or excessive panting due to respiratory distress.

### What Are Urinary Tract Obstructions?

An obstruction is anything that prevents urine from flowing freely through your cat's ureters and bladder – such as crystals, stones, inflammation, scarring or narrowed areas in the tubes themselves (such as strictures). A blockage can occur anywhere along this pathway. Urinary tract obstructions are more commonly seen in male cats than females because their ureters are shorter and narrower compared to female cats' ureters, which makes them more susceptible to blockages. They most often occur with the formation of crystals or small stones (uroliths) within your cat's bladder, but a number of other conditions can also cause this problem such as tumors and inflammation in her urinary tract. A urethral obstruction is one that occurs when something gets stuck in the urethra, which connects her bladder to the outside world (where she urinates). This condition can develop suddenly or gradually over time due to a buildup of crystals and stones within her urinary tract. In cats, these usually form as struvite (which has calcium phosphate) or calcium oxalate stones, although other types of uroliths are possible (such as ammonium biurate). Other causes include:

- Urethral swelling due to inflammation. This is often associated with bladder infections and conditions such as feline lower urinary tract disease (FLUTD) and neoplasia – abnormal growths of tissue within the urinary tract that can be cancerous or non-cancerous.
- Structural defects, which can include narrowing caused by scar tissue from previous surgeries (surgical removal) to correct other issues such as bladder stones and tumors in her urethra. These obstructions may develop suddenly if your cat has a history of urinary tract problems or chronic conditions affecting the kidneys, liver, adrenal glands or pancreas (which can lead to imbalances in electrolytes that are important for normal crystal formation).

### How Are Urinary Tract Obstructions Diagnosed?

A veterinarian will use a combination of physical examination findings and diagnostic testing – including blood work, urinalysis, X-rays, ultrasounds and sometimes advanced imaging techniques such as computed tomography (CT) scans or magnetic resonance imaging (MRI). Blood tests may reveal abnormal kidney values (elevated levels of creatinine, urea nitrogen or phosphorus), which indicate that your cat is experiencing reduced blood flow through her kidneys due to the blockage. Urinalysis can also show elevated protein levels and presence of bacteria in her urine, as well as crystals – indicating a possible obstructive process (such as urolithiasis). X-rays may reveal visible evidence of stones within your cat's bladder or along the urethra that are causing an obstruction. An ultrasound can provide more information about her urinary tract, and advanced imaging techniques such as CT scans and MRIs can help identify structural abnormalities (such as strictures) in your pet's urinary tract that may be contributing to the problem.

### How Are Urinary Tract Obstructions Treated?

Your veterinarian will recommend immediate hospitalization for treatment of a urethral obstruction, especially if her clinical signs are

severe or she shows signs of shock (decreased blood pressure, weak pulse and rapid breathing). The first step is to relieve the obstruction by flushing it out with a special catheter inserted through your cat's urethra. She may also receive fluids intravenously via an IV line to help rehydrate her body as well as medications for pain relief and nausea (if she is vomiting). Following the initial stabilization, surgical intervention may be necessary depending on how severe the obstruction was. Surgery can remove stones or crystals lodged within your pet's bladder using a cystoscope – an instrument that provides visual access to her urinary tract and allows for direct removal of these obstructions (such as urethral stent placement). If the obstruction was caused by strictures, she may need surgical correction or laser ablation therapy to open up any narrowed areas along the ureters. Once your cat has been treated and stabilized, her treatment plan will likely include medications such as:

- A diet that helps dissolve stones (this is typically prescribed for calcium oxalate uroliths) or prevents their recurrence;
- Medication to control pain after surgery if she experiences it;
- Anti-inflammatory drugs and antibiotics for any underlying conditions contributing to the obstruction such as FLUTD, bladder infections or neoplasia.

Your veterinarian will also recommend frequent rechecks of your pet's urine over several weeks to monitor her progress and ensure that there are no complications from surgery. She may need additional X-rays, ultrasounds or lab work during this time as well in order to make sure everything is healing correctly.

### How Can I Prevent Urinary Tract Obstructions?

Prevention of urinary tract obstructions begins with recognizing risk factors and early intervention when they occur:

- Maintain a healthy weight for your cat (obesity increases the chances that she will develop bladder infections).
- Provide plenty of fresh water daily to encourage more frequent urination; this helps flush out crystals before they can form.
- Feed her prescription diets designed to prevent stone formation if your veterinarian has diagnosed a predisposition towards developing stones based on blood and/or urine testing (these types of specialized diets are available for all three main types of uroliths – calcium oxalate, struvite and ammonium biurate).
- Increase water intake with wet foods or additional water bowls in your home. If she's dehydrated due to vomiting (often associated with obstructions), you can give her small amounts of Pedialyte to help replenish electrolytes that are important for normal crystal formation – just make sure it doesn't contain added sugar!
- Monitor your pet closely if she has a history of urinary tract problems or chronic conditions affecting the kidneys, adrenal glands, pancreas or other related systems. Consult with your veterinarian about medications such as allopurinol (for gout) that may help prevent crystal formation in certain cases – just make sure they don't interact negatively with any of her current medications before starting new ones!
- Ensure regular vet visits for screening and monitoring if your pet is at increased risk due to these factors.

The following are some signs that could indicate an urinary tract problem in cats:

- Straining or difficulty urinating;
- Blood on the fur around her genitals (from straining);
- Crystallized deposits inside or outside of the urethral opening (called "Feline Urologic Syndrome" - FUS) caused by a food ingredient called magnesium ammonium phosphate;
- Vomiting, diarrhea and/or lethargy which may indicate kidney disease or failure.

If you notice any of these signs in your cat, contact your veterinarian as soon as possible for an examination and appropriate testing to diagnose the problem and start treatment.

Support Content: Work Content: Prevention of Urinary Tract Obstructions in Cats

Urinary tract obstructions can be a serious condition that affects cats, causing discomfort and potential health complications. There are several measures you can take to prevent these obstructions from occurring or recurring. Here's what you need to know:

**Maintain a Healthy Weight:** Overweight or obese cats are more prone to developing urinary tract problems, including obstructions. Ensure your cat maintains an appropriate weight by providing a balanced diet and regular exercise.

**Promote Proper Hydration:** Dehydration can contribute to crystal formation in the urine, leading to potential obstructions. Always provide fresh water for your cat and consider adding more water bowls around the home or using a pet fountain to encourage drinking.

**Choose Appropriate Diets:** Feed your cat high-quality diets designed specifically for preventing urinary tract stones, which may include restricted amounts of certain ingredients like magnesium and phosphorus that contribute to stone formation. Consult with your veterinarian about the best options available based on your cat's specific needs.

**Monitor Urination Habits:** Pay close attention to changes in your cat's urination habits, such as straining or difficulty urinating, blood-tinged urine, crystallized deposits around the genitals, vomiting, diarrhea, and lethargy. These could be signs of urinary tract problems, including obstructions. Seek immediate veterinary care if you notice any abnormalities or changes in your cat's behavior.

**Schedule Regular Vet Visits:** Cats with a history of urinary tract issues or chronic conditions affecting the kidneys and related systems require regular check-ups to monitor their health status closely. Early detection and prompt treatment can prevent recurrent obstructions and other complications. Be proactive in scheduling visits for screening and monitoring based on your cat's needs, medical history, and risk factors.

**Create a Stress-Free Environment:** Stressful situations like changes to the household or environment may trigger urinary problems in cats. Make sure your cat feels comfortable by providing safe spaces, maintaining regular routines, and using calming products as recommended by your veterinarian. A stress-free environment can help reduce the likelihood of developing feline urologic syndrome (FUS) - a potential contributor to urinary tract obstructions.

In summary, prevention of urinary tract obstructions in cats involves maintaining a healthy weight and lifestyle for your cat, encouraging proper hydration, feeding appropriate diets, monitoring urination habits, scheduling regular vet visits, and minimizing stress in their environment. Taking these proactive measures can help keep your cat's urinary tract healthy and reduce the risk of obstructions or related complications.
